# Selecting the Population Most Close to a Control via Empirical Bayes Approach 

TACHEN LIANG ${ }^{1}$ AND WEN-TAO HUANG ${ }^{2}$<br>${ }^{1}$ Department of Mathematics, Wayne State University, Detroit, Michigan, USA<br>${ }^{2}$ Department of Management Sciences and Decision Making, Tamkang University, Taiwan, ROC

#### Abstract

This article deals with the problem of selecting the population most equivalent to a control from among $k$ independent normal populations using the parametric empirical Bayes approach. By combining useful information from the past data, an empirical Bayes selection procedure $P_{n}^{*}$ is studied. It is proved that the regret of $P_{n}^{*}$ converges to zero at a rate $O\left(\frac{\ln n}{n}\right)$, where $n$ is the number of past observations at hand. A simulation study is carried out to investigate the performance of $P_{n}^{*}$ for small to moderate values of $n$.

Keywords Asymptotically optimal; Bayes selection procedure; Empirical Bayes; Equivalent to a control; Rate of convergence; Regret.

Mathematics Subject Classification Primary 62F07; Secondary 62C12, 62C10.

## 1. Introduction

Problems of selecting populations equivalent to a control arise frequently in many applications. For example, in the industrial manufacturing process, suppose there are $k$ different methods of producing certain product. For a specific characteristic of an item, it is required that its measurement should be in certain specification limits (a control). Since the procedure of producing an item is complicated, the measurement of this characteristic is thus a random variable that involves several factors. We are mainly interested in selecting certain way of producing so that its associated mean of the specific characteristic is the best fit to the specification limits. For related applications, it is referred to Romano (1977) for instance. In a toxicological study, as described by Wellek and Michaelis (1991), such a selection problem arises in drug clinical trials and bioavailability trials. Consider $k$ different ways of producing drug for certain symptom and we need only to develop one of them. From a medical study, a response of some characteristic should reach a certain quantity (a control) so that the symptom can be removed.

However, if the response is more than that quantity, there will be some side effect. Under this situation we need to choose certain one from those $k$ different ways so that the response from body using this drug is the most close to this quantity.

In the literature, Gupta and Singh (1979) and Gupta and Hsiao (1981) proposed Bayes, $\Gamma$-minimax, and minimax procedures for selecting populations close to a control. Mee et al. (1987) developed multiple testing procedures to compare the means of $k$ normal populations with respect to a control. Giani and Strassburger (1994) studied testing and selection procedures for equivalence of $k$ populations with respect to a control. Dunnett and Gent (1977) developed tests to establish equivalence between treatments. Lakshminarayanan et al. (1994) studied multi-stage test procedures for testing Blackwelder's hypothesis of equivalence. Chen et al. (1993) derived range tests for the dispersion of several location parameters. Chen and Chen (1999) investigated a range test for the equivalence of means under unequal variances. Liang (1997, 2006) derived empirical Bayes procedures for selecting populations close to a control.

Consider $k$ independent normal populations $\pi_{1}, \ldots, \pi_{k}$, where $\pi_{i}$ has an unknown mean $\theta_{i}$ and an unknown variance $\sigma_{i}^{2}, i=1, \ldots, k$. For a fixed known control level $\theta_{0}$, let $\delta_{i}=\left(\theta_{i}-\theta_{0}\right)^{2}$ denote the distance between $\pi_{i}$ and the control $\theta_{0}$. For a given constant $\delta_{0}>0, \pi_{i}$ is said to be close to the control $\theta_{0}$ if $\delta_{i} \leq \delta_{0}$, and otherwise if $\delta_{i}>\delta_{0}$. Also, let $\delta_{[1]} \leq \cdots \leq \delta_{[k]}$ denote the ordered values of $\delta_{1}, \ldots, \delta_{k}$. The exact pairing between the ordered and the unordered parameters is of course unknown. The population $\pi_{i}$ with $\delta_{i}=\delta_{[1]}$ is called the population most close to the control $\theta_{0}$ if it is close to $\pi_{0}$. It is our main interest to select the population most close to the control. If there is no such population, we select none.

In this article, we employ the parametric empirical Bayes approach for our problem and it is organized as follows. The framework of the selection problem is introduced in Sec. 2. A Bayes selection procedure is derived. By mimicking the behavior of the Bayes procedure, we propose an empirical Bayes selection procedure $P_{n}^{*}$ in Sec. 3. The asymptotic optimality of $P_{n}^{*}$ is studied in Sec. 4. It is shown that the regret of $P_{n}^{*}$ converges to zero at a rate $O\left(\frac{\ln n}{n}\right)$, where $n$ is the number of past data available when the current selection problem is considered. A simulation study is carried out to investigate the performance of $P_{n}^{*}$ for small to moderate values of $n$. The simulated results are reported in Sec. 5. A detailed proof of the asymptotic optimality of $P_{n}^{*}$ are provided in Appendices A and B.

## 2. The Selection Problem and A Bayes Selection Procedure

Let $\Omega=\left\{\theta=\left(\theta_{1}, \ldots, \theta_{k}\right) \mid-\infty<\theta_{i}<\infty, i=1, \ldots, k\right\}$ be the parameter space.
Let $\underset{\sim}{a}=\left(a_{0}, a_{1}, \ldots, a_{k}\right)$ be an action where $a_{i}=0,1 ; i=0,1, \ldots, k$, and $\sum_{i=0}^{k} a_{i}=1$. For $a_{i}=1 \quad(i \neq 0)$, it means that $\pi_{i}$ is selected as the population closest to and equivalent to the control $\theta_{0}$. When $a_{0}=1$, it means that none is equivalent to the control and thus none is selected. We consider the following loss function:

$$
\begin{equation*}
L(\underset{\sim}{\theta}, \underset{\sim}{a})=\sum_{i=0}^{k} a_{i} \delta_{i}-\min \left(\delta_{[1]}, \delta_{0}\right) . \tag{2.1}
\end{equation*}
$$

Since $\theta_{0}$ is known, without loss of generality, we let $\theta_{0}=0$.
For each $i=1, \ldots, k$, let $X_{i 1}, \ldots, X_{i m}$ be a sample of size $m(m \geq 2)$ from $\pi_{i}$ and let $Y_{i}$ denote its sample mean. For its simplicity, for given $\left(\theta_{i}, \sigma_{i}^{2}\right)$, let $h_{i}\left(y_{i} \mid \theta_{i}\right)$
denote the probability density function (pdf) of $Y_{i}$, i.e., $N\left(\theta_{i}, \frac{\sigma_{i}^{2}}{m}\right.$. We are dealing with Bayes and empirical Bayes selection procedures regarding the parameters $\underset{\sim}{\theta}$. It suffices to consider selection procedures based on $\underset{\sim}{Y}=\left(Y_{1}, \ldots, Y_{k}\right)$, the sufficient statistics for $\theta$.

Consider that the parameter $\theta_{i}$ is a realization of a random variable $\Theta_{i}$ which has $N\left(\theta_{0}, \tau_{i}^{2}\right)$ as its prior distribution with unknown variance $\tau_{i}^{2}$. The random variables $\Theta_{1}, \ldots, \Theta_{k}$ are assumed to be independent. Thus, $Y_{i}$ has a marginal $N\left(\theta_{0}, \frac{\sigma_{i}^{2}}{m}+\tau_{i}^{2}\right)$ distribution and the corresponding marginal pdf is denoted by $h_{i}\left(y_{i}\right)$. Given $Y_{i}=y_{i}, \Theta_{i}$ follows a posterior $N\left(\left(1-B_{i}\right) y_{i},\left(1-B_{i}\right) \frac{\sigma_{i}^{2}}{m}\right)$ with $B_{i}=\frac{\sigma_{i}^{2}}{m} /$ $\left(\frac{\sigma_{i}^{2}}{m}+\tau_{i}^{2}\right)$.

Let $\mathscr{Y}$ be the sample space of $\underset{\sim}{Y}$. A selection procedure $p=\left(p_{0}, p_{1}, \ldots, p_{k}\right)$ is a mapping defined on $\mathscr{Y}$ into the product space $[0,1]^{k+1}$ such that for each $y$ in $\mathscr{Y}$, $\underset{\sim}{p}(\underset{\sim}{y})=\left(p_{0}(\underset{\sim}{y}), \ldots, p_{k}(\underset{\sim}{y})\right)$, where $p_{i}(\underset{\sim}{y})$ is the probability of selecting $\pi_{i}$ as $\tilde{\sim}$ the one $\tilde{c} \tilde{\sim}$ cosest to and equivalent to the control $\theta_{0}=0 ; p_{0}(y)$ is the probability of selecting none, with $\sum_{i=0}^{k} p_{i}(y)=1$. Under the error loss of $(2.1)$, the Bayes risk of a selection procedure $\underset{\sim}{p}$ is accordingly,

$$
\begin{align*}
R(\underset{\sim}{p}) & =\int_{\Omega} \int_{y}\left[\sum_{i=0}^{k} p_{i}(\underset{\sim}{y}) \delta_{i}-\min \left(\delta_{[1]}, \delta_{0}\right)\right] h(\underset{\sim}{y} \underset{\sim}{\theta}) d y d \underset{\sim}{\Pi}(\underset{\sim}{\theta}) \\
& =\int_{y}\left[p_{0}(\underset{\sim}{y}) \delta_{0}+\sum_{i=1}^{k} p_{i}(\underset{\sim}{y}) \psi_{i}\left(y_{i}\right)\right] h(\underset{\sim}{y}) d \underset{\sim}{y}-C, \tag{2.2}
\end{align*}
$$

where $h(y \mid \underset{\sim}{\theta})=\prod_{i=1}^{k} h_{i}\left(y_{i} \mid \theta_{i}\right), h(y)=\prod_{i=1}^{k} h_{i}\left(y_{i}\right), \Pi(\underset{\sim}{\theta})=\prod_{i=1}^{k} \pi_{i}\left(\theta_{i}\right)$ where $\pi_{i}\left(\theta_{i}\right)$ denotes $\tilde{N}\left(\theta_{0}, \tau_{i}^{2}\right), C=\int_{\Omega} \min \left(\delta_{[1]}, \tilde{\delta}_{0}\right) d \Pi(\underset{\sim}{\theta})$, and

$$
\begin{equation*}
\psi_{i}\left(y_{i}\right)=E\left[\Theta_{i}^{2} \mid Y_{i}=y_{i}\right]=\left(1-B_{i}\right) \frac{\sigma_{i}^{2}}{m}+\left(1-B_{i}\right)^{2} y_{i}^{2} \tag{2.3}
\end{equation*}
$$

### 2.1. A Bayes Selection Procedure

For each $y$ in $\mathscr{Y}$, let

$$
I(\underset{\sim}{y})=\left\{i \mid \psi_{i}\left(y_{i}\right)=\min _{1 \leq j \leq k} \psi_{j}\left(y_{j}\right) \text { and } \psi_{i}\left(y_{i}\right) \leq \delta_{0}\right\} .
$$

Define

$$
i_{B} \equiv i_{B}(\underset{\sim}{y})= \begin{cases}\min \{j \mid j \in I(\underset{\sim}{y})\} & \text { if } I(\underset{\sim}{y}) \neq \phi,  \tag{2.4}\\ 0 & \text { if } I(\underset{\sim}{y})=\phi .\end{cases}
$$

A Bayes selection procedure $P_{B}=\left(p_{B_{0}}, \ldots, p_{B_{k}}\right)$ which minimizes the Bayes risks $R(p)$ among all selection procedures can be obtained as follows:

For each $y$ in $\mathscr{y}$ and $i=0,1, \ldots, k$,

$$
p_{B_{i}}(\underset{\sim}{y})= \begin{cases}1 & \text { if } i=i_{B},  \tag{2.5}\\ 0 & \text { otherwise } .\end{cases}
$$

The minimum Bayes risk of this selection problem is:

$$
\begin{equation*}
R\left(P_{B}\right)=\int_{\mathscr{Y}}\left[\sum_{i=1}^{k} p_{B_{i}}(\underset{\sim}{y}) \psi_{i}\left(y_{i}\right)+p_{B_{0}}(\underset{\sim}{y}) \delta_{0}\right] h(\underset{\sim}{y}) d \underset{\sim}{y}-C . \tag{2.6}
\end{equation*}
$$

## 3. The Proposed Empirical Bayes Selection Procedures

It is noted that the Bayes selection procedure $P_{B}$ depends on the unknown parameters $\tau_{i}^{2}$ and $\sigma_{i}^{2}$. It is thus impossible to implement the Bayes selection procedure $P_{B}$. In the empirical Bayes framework, it is assumed that certain past data are available when the present selection problem is considered. Let $X_{i j e}$, $j=1, \ldots, m$, denote a sample of size $m$ from $\pi_{i}$ at stage $\ell, \ell=1,2, \ldots$ It is assumed that conditioning on $\left(\theta_{i \ell}, \sigma_{i}^{2}\right), X_{i j \ell}, j=1, \ldots, m$, are iid $N\left(\theta_{i \ell}, \sigma_{i}^{2}\right)$ and $\theta_{i \ell}$ is a realization of a random variable $\Theta_{i \ell}$, which has $N\left(\theta_{0}, \tau_{i}^{2}\right)$ as its prior. For each $i=1, \ldots, k$, we assume that $\left(\left(X_{i 1 l}, \ldots, X_{i m l}\right), \Theta_{i \ell}\right), l=1, \ldots, n$, are independent. It is also assumed that $\Theta_{i \ell}, i=1, \ldots, k, \ell=1,2, \ldots$ are mutually independent. For ease of notation, we consider the current stage as stage $n+1$ and denote $X_{i j n+1}$ by $X_{i j}, j=1, \ldots, m, i=1, \ldots, k$. Thus, $X_{i j \ell}, i=1, \ldots, k, j=1, \ldots, m, \ell=1, \ldots, n$ are the past data. Denote $\theta_{i}=\theta_{i, n+1}$ as a realization of the current random variable $\Theta_{i, n+1}, i=1, \ldots, k$ and let $\underset{\sim}{\theta}=\left(\theta_{1}, \ldots, \theta_{k}\right)$.

For each $\pi_{i}, i=1, \ldots, k$, and $\ell=1, \ldots, n$, denote $X_{i . \ell}=\frac{1}{m} \sum_{j=1}^{m} X_{i j \ell}, W_{i \ell}=$ $\frac{1}{m-1} \sum_{j=1}^{m}\left(X_{i j \ell}-X_{i . \ell}\right)^{2}$. Note that $X_{i . \ell}$ and $W_{i \ell}$ are mutually independent, $X_{i, \ell}$ has a marginal $N\left(\theta_{0}, \frac{\sigma_{i}^{2}}{m}+\tau_{i}^{2}\right)$ distribution, and $\frac{(m-1) W_{i e}}{\sigma_{i}^{2}}$ follows a $\chi_{(m-1)}^{2}$ distribution. Define $S_{i}(n)=\frac{1}{n} \sum_{\ell=1}^{n}\left(X_{i . \ell}-\theta_{0}\right)^{2}$, and $W_{i}(n)=\frac{1}{n} \sum_{\ell=1}^{n} W_{i \ell}$. Thus, $S_{i}(n)$ and $W_{i}(n)$ are independent, $\frac{n S_{i}(n)}{\tau_{i}^{2}+\sigma_{i}^{2} / m} \sim \chi_{(n)}^{2}, \frac{(m-1) n W_{i}(n)}{\sigma_{i}^{2}} \sim \chi_{(n(m-1))}^{2}$. Thus, $E S_{i}(n)=\frac{\sigma_{i}^{2}}{m}+\tau_{i}^{2}$ and $E W_{i}(n)=\sigma_{i}^{2}$. So, we use $S_{i}(n)$ to estimate $\frac{\sigma_{i}^{2}}{m}+\tau_{i}^{2}$ and $W_{i}(n)$ to estimate $\sigma_{i}^{2}$. We may use $\frac{W_{i}(n) / m}{S_{i}(n)}$ to estimate $B_{i}=\frac{\sigma_{i}^{2}}{m} /\left(\frac{\sigma_{i}^{2}}{m}+\tau_{i}^{2}\right)$. Since $0<B_{i}<1$, we define $B_{i n}=\min \left(\frac{W_{i}(n) / m}{S_{i}(n)}, 1\right)$ and use $B_{i n}$ as an estimator of $B_{i}$. Now, mimicking the form (2.3), we propose an estimator $\psi_{i n}\left(y_{i}\right)$ for $\psi_{i}\left(y_{i}\right)$, where

$$
\begin{equation*}
\psi_{i n}\left(y_{i}\right)=\left(1-B_{i n}\right) \frac{W_{i}(n)}{m}+\left(1-B_{i n}\right)^{2} y_{i}^{2} . \tag{3.1}
\end{equation*}
$$

Now, for each $y$ in $\mathscr{Y}$, define

$$
\begin{equation*}
I_{n}(\underset{\sim}{y})=\left\{i \mid \psi_{i n}\left(y_{i}\right)=\min _{1 \leq j \leq k} \psi_{j n}\left(y_{j}\right), \psi_{i n}\left(y_{i}\right) \leq \delta_{0}\right\} . \tag{3.2}
\end{equation*}
$$

and

$$
i_{n}^{*} \equiv i_{n}^{*}(\underset{\sim}{y})= \begin{cases}\min I_{n}(\underset{\sim}{y}) & \text { if } I_{n}(\underset{\sim}{y}) \neq \phi,  \tag{3.3}\\ 0 & \text { if } I_{n}(\underset{\sim}{y})=\phi\end{cases}
$$

We propose an empirical Bayes selection procedure $P_{n}^{*}=\left(p_{n 0}^{*}, p_{n 1}^{*}, \ldots, p_{n k}^{*}\right)$ based on $i_{n}^{*}$ as follows:

For each $y$ in $\mathscr{Y}$,

$$
p_{n i}^{*}(\underset{\sim}{y})= \begin{cases}1 & \text { if } i=i_{n}^{*},  \tag{3.4}\\ 0 & \text { otherwise } .\end{cases}
$$

We note that $P_{n}^{*}$ is an empirical Bayes selection procedure based on the past data $\left\{X_{i j \ell}, i=1, \ldots, k ; j=1, \ldots, m, \ell=1, \ldots, n\right\}$ only through $\underset{\sim}{\underset{\sim}{W}} \underset{(n)}{\underset{S}{S}}(n)=$ $\left(W_{1}(n), \ldots, W_{k}(n)\right)$ and $\underset{\sim}{S}(n)=\left(S_{1}(n), \ldots, S_{k}(n)\right)$. Conditioning on $\underset{\sim}{W}(n)$ and $\underset{\sim}{S}(n)$, the conditional Bayes risk of $P_{n}^{*}$ is

$$
R\left(P_{n}^{*} \mid \underset{\sim}{W}(n), \underset{\sim}{S}(n)\right)=\int_{y}\left[\sum_{i=1}^{k} p_{n i}^{*}(\underset{\sim}{y}) \psi_{i}\left(y_{i}\right)+p_{n 0}^{*}(\underset{\sim}{y}) \delta_{0}\right] h(\underset{\sim}{y}) d \underset{\sim}{y}-C .
$$

The (unconditional) Bayes risk of $P_{n}^{*}$ is thus,

$$
\begin{align*}
R\left(P_{n}^{*}\right) & =E_{n} R\left(P_{n}^{*} \mid \underset{\sim}{W}(n), \underset{\sim}{S}(n)\right) \\
& =\int_{\mathscr{y}}\left[\sum_{i=1}^{k} E_{n}\left[p_{n i}^{*}(\underset{\sim}{y})\right] \psi_{i}\left(y_{i}\right)+E_{n}\left[p_{n 0}^{*}(\underset{\sim}{y}) \delta_{0}\right]\right] h(\underset{\sim}{y}) d \underset{\sim}{y}-C, \tag{3.5}
\end{align*}
$$

where the expectation $E_{n}$ is taken with respect to the probability measure generated by $(\underset{\sim}{W}(n), \underset{\sim}{S}(n))$.

## 4. Asymptotic Optimality

In this section, we study the asymptotic optimality of the empirical Bayes selection procedure $P_{n}^{*}$. For an empirical Bayes selection procedure $P_{n}$, let $R\left(P_{n} \mid \underset{\sim}{W}(n), \underset{\sim}{S}(n)\right)$ and $R\left(P_{n}\right)$ denote its corresponding conditional and unconditional Bayes risks, respectively. Since $R\left(P_{B}\right)$ is the minimum Bayes risk, $R\left(P_{n} \mid \underset{\sim}{W}(n), \underset{\sim}{S}(n)\right)-R\left(P_{B}\right) \geq 0$ for all ( $W(n), S(n)$ ) and $n$, therefore, $R\left(P_{n}\right)-R\left(P_{B}\right) \geq 0$ for all $n$. The non negative difference $R\left(P_{n}\right)-R\left(P_{B}\right)$, the regret of the selection procedure $P_{n}$, is usually used as a measure of performance of the selection procedure $P_{n}$. An empirical Bayes selection procedure $P_{n}$ is said to be asymptotically optimal of order $O\left(\varepsilon_{n}\right)$ if $R\left(P_{n}\right)-$ $R\left(P_{B}\right)=O\left(\varepsilon_{n}\right)$, where $\left\{\varepsilon_{n}\right\}$ is a sequence of positive numbers decreasing to zero.

From (2.5)-(2.6) and (3.3)-(3.5), the regret of $P_{n}^{*}$ can be expressed as

$$
\begin{aligned}
& R\left(P_{n}^{*}\right)-R\left(P_{B}\right) \\
& \quad=\int_{\mathscr{y}} \sum_{\substack{i=1 \\
j \neq i}}^{k} \sum_{j=1}^{k} P\left\{i_{n}^{*}(\underset{\sim}{y})=i, i_{B}(\underset{\sim}{y})=j\right\}\left[\psi_{i}\left(y_{i}\right)-\psi_{j}\left(y_{j}\right)\right] h(\underset{\sim}{y}) d \underset{\sim}{y}
\end{aligned}
$$

$$
\begin{align*}
& +\int_{y} \sum_{i=1}^{k} P\left\{i_{n}^{*}(\underset{\sim}{y})=i, i_{B}(\underset{\sim}{y})=0\right\}\left[\psi_{i}\left(y_{i}\right)-\delta_{0}\right] h(\underset{\sim}{y}) d \underset{\sim}{y} \\
& +\int_{y} \sum_{j=1}^{k} P\left\{i_{n}^{*}(\underset{\sim}{y})=0, i_{B}(\underset{\sim}{y})=j\right\}\left[\delta_{0}-\psi_{j}\left(y_{j}\right)\right] h(\underset{\sim}{y}) d \underset{\sim}{y} . \tag{4.1}
\end{align*}
$$

Note that if $\left(1-B_{i}\right) \frac{\sigma_{i}^{2}}{m} \geq \delta_{0}$, then $\psi_{i}\left(y_{i}\right) \geq \delta_{0}$ for all $y_{i}$. In the following analysis, it is assumed that $\left(1-B_{i}\right) \frac{\sigma_{i}^{2}}{m}<\delta_{0}$ for each $i=1, \ldots, k$. Let $a_{i}=$ $\sqrt{\delta_{0}-\left(1-B_{i}\right) \frac{\sigma_{i}^{2}}{m}} /\left(1-B_{i}\right)$. Thus, $\psi_{i}\left(y_{i}\right)<\delta_{0}$ if, and only if, $\left|y_{i}\right|<a_{i}$ and $\psi_{i}\left(a_{i}\right)=\delta_{0}$, and $\psi_{i}\left(y_{i}\right)>\delta_{0}$ if, and only if, $\left|y_{i}\right|>a_{i}$. Let $A_{i}=\left(-a_{i}, a_{i}\right)$ and $A_{i}^{c}=\left(-\infty,-a_{i}\right] \cup$ $\left[a_{i}, \infty\right)$. Therefore, $i_{B}(y)=0$ if, and only if, $\left|y_{i}\right|>a_{i}$ for all $i=1, \ldots, k$. Hence, by the definition of $i_{n}^{*}$ and $i_{B}$, we have

$$
\begin{gather*}
\int_{\mathscr{y}} P\left\{i_{n}^{*}(\underset{\sim}{y})=i, i_{B}(\underset{\sim}{y})=0\right\}\left[\psi_{i}\left(y_{i}\right)-\delta_{0}\right] h(\underset{\sim}{y}) d \underset{\sim}{y} \\
\leq \int_{A_{i}^{c}} P\left\{\psi_{i n}\left(y_{i}\right)<\delta_{0}\right\}\left[\psi_{i}\left(y_{i}\right)-\delta_{0}\right] h_{i}\left(y_{i}\right) d y_{i} . \tag{4.2}
\end{gather*}
$$

and

$$
\begin{align*}
& \left.\int_{\mathscr{y}} P\left\{i_{n}^{*}(\underset{\sim}{y})=0, \underset{\sim}{i}{\underset{\sim}{B}}_{(y)}^{y}\right)=j\right\}\left[\delta_{0}-\psi_{j}\left(y_{j}\right)\right] h(\underset{\sim}{y}) d \underset{\sim}{y} \\
& \leq \int_{A_{j}} P\left\{\psi_{j n}\left(y_{j}\right) \geq \delta_{0}\right\}\left[\delta_{0}-\psi_{j}\left(y_{j}\right)\right] h_{j}\left(y_{j}\right) d y_{j} . \tag{4.3}
\end{align*}
$$

Define $A_{i j}=\left\{\left(y_{i}, y_{j}\right)| | y_{j} \mid \leq a_{j}, \psi_{i}\left(y_{i}\right)-\psi_{j}\left(y_{j}\right)>0\right\}$. For $\left(y_{i}, y_{j}\right) \in A_{i j}$, let $t\left(y_{i}, y_{j}\right) \equiv$ $\left(\psi_{i}\left(y_{i}\right)-\psi_{j}\left(y_{j}\right)\right) / 6>0$. Thus, for each $\underset{\sim}{y}$ such that $i_{B}(\underset{\sim}{y})=j$ and $\psi_{i}\left(y_{i}\right)>\psi_{j}\left(y_{j}\right)$, the related $\left(y_{i}, y_{j}\right)$ must be in $A_{i j}$. Hence,

$$
\begin{aligned}
P\left\{i_{n}^{*}(\underset{\sim}{y})=i, i_{B}(\underset{\sim}{y})=j\right\} \leq & P\left\{\psi_{i n}\left(y_{i}\right)-\psi_{j n}\left(y_{j}\right) \leq 0\right\} \\
= & P\left\{\left[\psi_{i n}\left(y_{i}\right)-\psi_{j n}\left(y_{j}\right)\right]-\left[\psi_{i}\left(y_{i}\right)-\psi_{j}\left(y_{j}\right)\right]<-6 t\left(y_{i}, y_{j}\right)\right\} \\
\leq & P\left\{\left[\psi_{i n}\left(y_{i}\right)-\psi_{i}\left(y_{i}\right)\right]<-3 t\left(y_{i}, y_{j}\right)\right\} \\
& +P\left\{\left[\psi_{j n}\left(y_{j}\right)-\psi_{j}\left(y_{j}\right)\right]>3 t\left(y_{i}, y_{j}\right)\right\} .
\end{aligned}
$$

Therefore,

$$
\begin{align*}
& \iint_{\mathscr{Y}} P\left\{\underset{\sim}{i} i_{n}^{*}(\underset{\sim}{y})=i,{\underset{\sim}{i}}_{B}(\underset{\sim}{y})=j\right\}\left[\psi_{i}\left(y_{i}\right)-\psi_{j}\left(y_{j}\right)\right] h(\underset{\sim}{y}) d \underset{\sim}{y} \\
& \leq \iint_{A_{i j}} P\left\{\left[\psi_{i n}\left(y_{i}\right)-\psi_{i}\left(y_{i}\right)\right]<-3 t\left(y_{i}, y_{j}\right)\right\} 6 t\left(y_{i}, y_{j}\right) h_{i}\left(y_{i}\right) h_{j}\left(y_{j}\right) d y_{i} d y_{j} \\
& \quad+\iint_{A_{i j}} P\left\{\left[\psi_{j n}\left(y_{j}\right)-\psi_{j}\left(y_{j}\right)\right]>3 t\left(y_{i}, y_{j}\right)\right\} 6 t\left(y_{i}, y_{j}\right) h_{i}\left(y_{i}\right) h_{j}\left(y_{j}\right) d y_{i} d y_{j} \tag{4.4}
\end{align*}
$$

Substituting the inequalities of (4.2)-(4.4) into (4.1), we obtain

$$
\begin{align*}
& R\left(P_{n}^{*}\right)-R\left(P_{B}\right) \\
& \quad \leq \sum_{i \neq j} \iint_{A_{i j}} P\left\{\left[\psi_{i n}\left(y_{i}\right)-\psi_{i}\left(y_{i}\right)\right]<-3 t\left(y_{i}, y_{j}\right)\right\} 6 t\left(y_{i}, y_{j}\right) h_{i}\left(y_{i}\right) h_{j}\left(y_{j}\right) d y_{i} d y_{j} \\
& \quad+\sum_{i \neq j} \sum_{A_{i j}} P\left\{\left[\psi_{j n}\left(y_{j}\right)-\psi_{j}\left(y_{j}\right)\right]>3 t\left(y_{i}, y_{j}\right)\right\} 6 t\left(y_{i}, y_{j}\right) h_{i}\left(y_{i}\right) h_{j}\left(y_{j}\right) d y_{i} d y_{j} \\
& \quad+\sum_{i=1}^{k} \int_{A_{i}^{c}} P\left\{\psi_{i n}\left(y_{i}\right)<\delta_{0}\right\}\left[\psi_{i}\left(y_{i}\right)-\delta_{0}\right] h_{i}\left(y_{i}\right) d y_{i} \\
& \quad+\sum_{j=1}^{k} \int_{A_{j}} P\left\{\psi_{j n}\left(y_{j}\right) \geq \delta_{0}\right\}\left[\delta_{0}-\psi_{j}\left(y_{j}\right)\right] h_{j}\left(y_{j}\right) d y_{j} \\
& =I+I I+I I I+I V . \tag{4.5}
\end{align*}
$$

Thus, to study the asymptotic optimality of $P_{n}^{*}$, it suffices to investigate the asymptotic behaviors of the four terms $I, I I, I I I$, and $I V$. It is noted that the analysis
of the four terms are similar, though the analysis of $I$ and $I I$ is somewhat more complicated than that of $I I I$ and $I V$. We thus provide only detailed analysis and discussion for the term of $I$ in Appendix A. It follows then that

$$
\begin{equation*}
I=O\left(\frac{\ln n}{n}\right) \tag{4.6}
\end{equation*}
$$

Following a similar analysis and discussion as that of $I$, we can also obtain the following results:

$$
\begin{align*}
I I & =O\left(\frac{\ln n}{n}\right)  \tag{4.7}\\
I I I & =O\left(\frac{1}{n}\right)  \tag{4.8}\\
I V & =O\left(\frac{1}{n}\right) \tag{4.9}
\end{align*}
$$

We summarize the preceding results as follows.

Table 2
For $m=30$ under $C_{32}$

Theorem 4.1. Suppose that $\left(1-B_{i}\right) \frac{\sigma_{i}^{2}}{m}<\delta_{0}$ for each $i=1, \ldots, k$. Let $P_{n}^{*}$ be the empirical Bayes selection procedure constructed in Sec. 3. Then, $P_{n}^{*}$ is asymptotically optimal and $R\left(P_{n}^{*}\right)-R\left(P_{B}\right)=O\left(\frac{\ln n}{n}\right)$.

## 5. Simulation Study

In this study, we consider two cases, i.e., $k=3$ and $k=5$, taking $\theta_{0}=0$.
For $k=3$, we consider two situations of its parameters:

$$
\begin{aligned}
& C_{31}: \sigma_{i}^{2}=1, \tau_{i}^{2}=i, i=1,2,3 \\
& C_{32}: \sigma_{i}^{2}=\tau_{i}^{2}=i, i=1,2,3 .
\end{aligned}
$$

And for $k=5$, we also consider two situations:

$$
\begin{aligned}
& C_{51}: \sigma_{i}^{2}=1, \tau_{i}^{2}=i, i=1,2,3,4,5 \\
& C_{52}: \sigma_{i}^{2}=\tau_{i}^{2}=i, i=1,2,3,4,5 .
\end{aligned}
$$

|  | 0.9987 | $3.253 \mathrm{E}-007$ | $1.271 \mathrm{E}-005$ |  |

All simulations are repeated 10,000 times. For stage $n$, we denote $f_{n}$ as the frequency of correct selection, $\bar{D}_{n}$ its corresponding average loss and $\operatorname{SE}\left(\bar{D}_{n}\right)$ the standard deviation of $\bar{D}_{n}$, where the correct selection means the event that the Bayes rule $P_{B}$ selects the same population which the empirical Bayes rule $P_{n}^{*}$ does.

In Table 1, we take $\delta_{0}=1$ under the case of $C_{31}$. The upper and lower entries are respectively associated with $m=30$ and $m=50$, the sample size of each population for each stage. In Table 2, we consider $m=30, \delta_{0}=1$ (upper entry) and $\delta_{0}=2$ (lower entry) under $C_{32}$.

To see the role of $\sigma_{i}^{2}$ in the frequency of correct selection in $C_{31}$, we define $\mathrm{U}\left(C_{32} / C_{31}\right)=f_{n}\left(C_{31}\right) / f_{n}\left(C_{32}\right)$, where $f_{n}\left(C_{3 i}\right)$ denotes the frequency of correct selection under $C_{3 i}$ when $\delta_{0}=1, m=30$ and $\sigma_{i}^{2}=1$, for $i=1,2$. The value of U is tabulated in the last column of Table 2.

In Table 3, we consider $\delta_{0}=1, m=30$ (upper entry) and $m=50$ (lower entry) under $C_{51}$. Values of $\mathrm{U}\left(C_{52} / C_{51}\right)$ are also tabulated for $\delta_{0}=1$ and $m=30$. For Table 4, we take $m=30$ and consider $\delta_{0}=2$ (upper entry) and $\delta_{0}=3$ (lower entry) under $C_{52}$.

To give some ideas how the expected loss behaves relating to stage number $n$, we define $r_{20}(n)=\frac{\bar{D}_{20}-\bar{D}_{n}}{\bar{D}_{20}}$, the percentage of the decrease of $\bar{D}_{n}$ with respect to

Figure 1. Plot of $r_{20}(n)$ under $C_{31}$.
$\bar{D}_{20}$ with $n=20$. Values of $r_{20}(n)$ are plotted in Figs. 1 and 2 for different values of $\delta_{0}$ and different configurations. For some given $\delta_{0}$ and configuration, to compare $r_{20}(n)$ for $m=30$ to that of $m=50$, we consider the ratio $R(n)=\frac{S_{30}(n)}{S_{50}(n)}, S_{30}(n)$ and $S_{50}(n)$ are, respectively, $r_{20}(n)$ for $m=30$ and $m=50$. We plot $R(n)$ respectively, for two different values of $\delta_{0}$ under different configuration in Figs. 3 and 4. To see the variations of expected loss with respect to sample size $m$ for given $n=20$

Figure 2. Plot of $r_{20}(n)$ under $C_{51}$.

Figure 3. Plot of $R(n)$ under $C_{31}$.
and $n=40$, respectively, we define $t_{5}(m)=\left(D_{5}-D_{m}\right) / D_{5}$, where $D_{m}$ denotes the expected loss $\bar{D}_{n}$ with sample size $m$ under some given $n . t(m)$ are plotted in Figs. 5 and 6 for $C_{31}$ and $C_{51}$, respectively.

It is easy to see that the expected loss becomes stable when $m \geq 35$ for both $C_{31}$ and $C_{51}$ and the frequency of correct selection seems stable, though it is slowly increasing in $n$, even for small $n$.

Figure 4. Plot of $R(n)$ under $C_{51}$.

Figure 5. Plot of $t_{5}(m)$ under $C_{31}$.

To see the effect of $\sigma_{i}^{2}$ for the frequency of correct selection, we can see that values of $\mathrm{U}\left(C_{32} / C_{31}\right)$ are stable and close to 1 for $\delta_{0}=1$ and $m=30$ for both small and large values of $n$. So is the case of $C_{52}$ against $C_{51}$.

To summarize, the expected loss depends heavily on $n$ and also on $\delta_{0}$, rather than $m$. It decreases steadily as $n$ increases. However, the rate of decrease closely relates to $m$ and $\delta_{0}$.

Figure 6. Plot of $t_{5}(\mathrm{~m})$ under $C_{51}$.

## Appendix A

Proof of $I=O\left(\frac{\ln n}{n}\right)$. Note that $I=\sum_{i=1}^{k} \sum_{j \neq i}^{k} I_{j=1} I_{i j}$, where

$$
\begin{equation*}
I_{i j}=\iint_{A_{i j}} P\left\{\left[\psi_{i n}\left(y_{i}\right)-\psi_{i}\left(y_{i}\right)\right]<-3 t\left(y_{i}, y_{j}\right)\right\} 6 t\left(y_{i}, y_{j}\right) h_{i}\left(y_{i}\right) h_{j}\left(y_{j}\right) d y_{i} d y_{j} \tag{A.1}
\end{equation*}
$$

By Lemma B. 3 (see Appendix B), for each $\left(y_{i}, y_{j}\right)$ in $A_{i j}$, and noting that $g_{1}(x) \equiv$ $x+\ln (1-x)$ for $0<x<1$ and $g_{2}(x) \equiv x-\ln (1+x)$ for $x>0$,

$$
\begin{align*}
& P\left\{\psi_{i n}\left(y_{i}\right)-\psi_{i}\left(y_{i}\right)<-3 t\left(y_{i}, y_{j}\right)\right\} \\
& \quad \leq \exp \left\{\frac{n(m-1)}{2} g_{1}\left(\frac{m t\left(y_{i}, y_{j}\right)}{\sigma_{i}^{2}}\right)\right\} I\left(\sigma_{i}^{2}-m t\left(y_{i}, y_{j}\right)\right) \\
& \quad+\exp \left\{\frac{-n(m-1)}{2} g_{2}\left(\frac{m t\left(y_{i}, y_{j}\right)}{2 B_{i} \sigma_{i}^{2}}\right)\right\} I\left(\left(1-B_{i}\right) \sigma_{i}^{2}-m t\left(y_{i}, y_{j}\right)\right) \\
& \quad+\exp \left\{\frac{n}{2} g_{1}\left(\frac{m t\left(y_{i}, y_{j}\right)}{2 B_{i} \sigma_{i}^{2}+2 m t\left(y_{i}, y_{j}\right)}\right)\right\} I\left(\left(1-B_{i}\right) \sigma_{i}^{2}-m t\left(y_{i}, y_{j}\right)\right) \\
& \quad+\exp \left\{\frac{-n(m-1)}{2} g_{2}\left(\frac{t\left(y_{i}, y_{j}\right)}{4 B_{i} y_{i}^{2}}\right)\right\} I\left(2\left(1-B_{i}\right) y_{i}^{2}-t\left(y_{i}, y_{j}\right)\right) \\
& \quad+\exp \left\{\frac{n}{2} g_{1}\left(\frac{t\left(y_{i}, y_{j}\right)}{4 B_{i} y_{i}^{2}+2 t\left(y_{i}, y_{j}\right)}\right)\right\} I\left(2\left(1-B_{i}\right) y_{i}^{2}-t\left(y_{i}, y_{j}\right)\right) . \tag{A.2}
\end{align*}
$$

Let

$$
\begin{align*}
A_{i j 1} & =\left\{\left(y_{i}, y_{j}\right) \in A_{i j} \mid \sigma_{i}^{2}-m t\left(y_{i}, y_{j}\right)>0, \quad y_{i}>0, \quad y_{j}>0\right\}, \\
A_{i j 2} & =\left\{\left(y_{i}, y_{j}\right) \in A_{i j} \mid\left(1-B_{i}\right) \sigma_{i}^{2}-m t\left(y_{i}, y_{j}\right)>0, \quad y_{i}>0, \quad y_{j}>0\right\}, \\
A_{i j 3} & =\left\{\left(y_{i}, y_{j}\right) \in A_{i j} \mid 2\left(1-B_{i}\right) y_{i}^{2}-t\left(y_{i}, y_{j}\right)>0, \quad y_{i}>0, \quad y_{j}>0\right\} .  \tag{A.3}\\
\alpha_{1}\left(y_{i}, y_{j}, n\right) & =24 \exp \left\{\frac{n(m-1)}{2} g_{1}\left(\frac{m t\left(y_{i}, y_{j}\right)}{\sigma_{i}^{2}}\right)\right\} t\left(y_{i}, y_{j}\right) h_{i}\left(y_{i}\right) h_{j}\left(y_{j}\right), \\
\alpha_{2}\left(y_{i}, y_{j}, n\right) & =24 \exp \left\{\frac{-n(m-1)}{2} g_{2}\left(\frac{m t\left(y_{i}, y_{j}\right)}{2 B_{i} \sigma_{i}^{2}}\right)\right\} t\left(y_{i}, y_{j}\right) h_{i}\left(y_{i}\right) h_{j}\left(y_{j}\right), \\
\alpha_{3}\left(y_{i}, y_{j}, n\right) & =24 \exp \left\{\frac{n}{2} g_{1}\left(\frac{m t\left(y_{i}, y_{j}\right)}{2 B_{i} \sigma_{i}^{2}+2 m t\left(y_{i}, y_{j}\right)}\right)\right\} t\left(y_{i}, y_{j}\right) h_{i}\left(y_{i}\right) h_{j}\left(y_{j}\right), \\
\alpha_{4}\left(y_{i}, y_{j}, n\right) & =24 \exp \left\{\frac{-n(m-1)}{2} g_{2}\left(\frac{t\left(y_{i}, y_{j}\right)}{4 B_{i} y_{i}^{2}}\right)\right\} t\left(y_{i}, y_{j}\right) h_{i}\left(y_{i}\right) h_{j}\left(y_{j}\right), \\
\alpha_{5}\left(y_{i}, y_{j}, n\right) & =24 \exp \left\{\frac{n}{2} g_{1}\left(\frac{t\left(y_{i}, y_{j}\right)}{4 B_{i} y_{i}^{2}+2 t\left(y_{i}, y_{j}\right)}\right)\right\} t\left(y_{i}, y_{j}\right) h_{i}\left(y_{i}\right) h_{j}\left(y_{j}\right) . \tag{A.4}
\end{align*}
$$

Substitute the inequality of (A.2) into (A.1). Note that $\psi_{i}\left(y_{i}\right)$ and $h_{j}\left(y_{j}\right)$ are symmetric about $\theta_{0}=0$. By this symmetry property, we obtain:

$$
I_{i j} \leq \iint_{A_{i j 1}} \alpha_{1}\left(y_{i}, y_{j}, n\right) d y_{i} d y_{j}+\iint_{A_{i j 2}} \alpha_{2}\left(y_{i}, y_{j}, n\right) d y_{i} d y_{j}+\iint_{A_{i j 2}} \alpha_{3}\left(y_{i}, y_{j}, n\right) d y_{i} d y_{j}
$$

$$
\begin{align*}
& +\iint_{A_{i 33}} \alpha_{4}\left(y_{i}, y_{j}, n\right) d y_{i} d y_{j}+\iint_{A_{i j 3}} \alpha_{5}\left(y_{i}, y_{j}, n\right) d y_{i} d y_{j} \\
= & J_{1}+J_{2}+J_{3}+J_{4}+J_{5} . \tag{A.5}
\end{align*}
$$

Let $S_{i j}=\left\{y_{j} \mid 0 \leq y_{j} \leq a_{j}, \psi_{i}(0)-\psi_{j}\left(y_{j}\right)>0\right\}$ and

$$
s_{i j}= \begin{cases}\max _{u \in S_{i j}} u & \text { if } S_{i j} \neq \phi \\ 0 & \text { if } S_{i j}=\phi\end{cases}
$$

Note that $\psi_{i}\left(y_{i}\right)$ is increasing in $y_{i}$ for $y_{i} \geq 0$.
Case 1. If $s_{i j}>0$, then for each $y_{i} \geq 0, \psi_{i}\left(y_{i}\right)-\psi_{j}\left(\frac{s_{i j}}{2}\right) \geq \psi_{i}(0)-\psi_{j}\left(\frac{s_{i j}}{2}\right) \equiv$ $c_{2}>0$.

Case 2. If $s_{i j}=0$, then $\psi_{i}(0)-\psi_{j}(0)=\left(1-B_{i}\right) \frac{\sigma_{i}^{2}}{m}-\left(1-B_{j}\right) \frac{\sigma_{j}^{2}}{m} \equiv c_{3} \leq 0$.
In the following, we study the asymptotic behaviors of the five terms $J_{i}$, $i=1,2,3,4,5$.

Case 1. If $s_{i j}>0$.
Let $D_{1}=\left\{\left(y_{i}, y_{j}\right) \in A_{i j 1} \left\lvert\, y_{j} \leq \frac{s_{i j}}{2}\right.\right\}$ and $C_{1}=\left\{\left(y_{i}, y_{j}\right) \in A_{i j 1} \left\lvert\, y_{j}>\frac{s_{i j}}{2}\right.\right\}$. Thus,

$$
\begin{equation*}
J_{1}=\iint_{D_{1}} \alpha_{1}\left(y_{i}, y_{j}, n\right) d y_{i} d y_{j}+\iint_{C_{1}} \alpha_{1}\left(y_{i}, y_{j}, n\right) d y_{i} d y_{j}=J_{11}+J_{12} . \tag{A.6}
\end{equation*}
$$

On $D_{1}, t\left(y_{i}, y_{j}\right) \geq t\left(0, \frac{s_{i j}}{2}\right)=\frac{c_{2}}{6}>0$. Since $g_{1}(x)$ is decreasing in $x$ for $0<x<1$, thus,

$$
\begin{align*}
J_{11} & \leq \iint_{D_{1}} 24 \exp \left(\frac{n(m-1)}{2} g_{1}\left(\frac{m c_{2}}{6 \sigma_{i}^{2}}\right)\right) t\left(y_{i}, y_{j}\right) h_{i}\left(y_{i}\right) h_{j}\left(y_{j}\right) d y_{i} d y_{j} \\
& =\exp \left(\frac{n(m-1)}{2} g_{1}\left(\frac{m c_{2}}{6 \sigma_{i}^{2}}\right)\right) \iint_{D_{1}} 24 t\left(y_{i}, y_{j}\right) h_{i}\left(y_{i}\right) h_{j}\left(y_{j}\right) d y_{i} d y_{j} \\
& \leq 4 \exp \left(\frac{n(m-1)}{2} g_{1}\left(\frac{m c_{2}}{6 \sigma_{i}^{2}}\right)\right) \tau^{\tau^{2}}, \tag{A.7}
\end{align*}
$$

where the last inequality is obtained due to Lemma B. 6 and where $\tau^{* 2}=\max _{i} \tau_{i}^{2}$ and $\tau_{i}^{2}=E \Theta_{i}^{2}$. Note that $g_{1}\left(\frac{m c_{2}}{6 \sigma_{i}^{2}}\right) \leq \frac{-1}{2}\left(\frac{m c_{2}}{6 \sigma_{i}^{2}}\right)^{2}<0$.

Again, note that $h_{i}\left(y_{i}\right)^{i} \leq \ell_{0}$ for all $y_{i}$, for some positive value $\ell_{0}$, and $i=1, \ldots, k$. On $C_{1},\left|\frac{\partial t\left(y_{i}, y_{j}\right)}{\partial y_{j}}\right|=\frac{2\left(1-B_{j}\right)^{2} y_{j}}{6} \geq \frac{\left(1-B_{j}\right)^{2} s_{i j}}{6}>0$. By using the preceding inequality, changing the variable by letting $x=\frac{m t\left(y_{i}, y_{j}\right)}{\sigma_{i}^{2}}$ and by Lemma B.4, we obtain

$$
\begin{align*}
J_{12}= & 24 \iint_{C_{1}} \exp \left\{\frac{n(m-1)}{2} g_{1}\left(\frac{m t\left(y_{i}, y_{j}\right)}{\sigma_{i}^{2}}\right)\right\} \frac{m t\left(y_{i}, y_{j}\right)}{\sigma_{i}^{2}}\left|\frac{\partial}{\partial y_{j}} \frac{m t\left(y_{i}, y_{j}\right)}{\sigma_{i}^{2}}\right| \frac{\sigma_{i}^{4}}{m^{2}} \\
& \times \frac{3 h_{j}\left(y_{j}\right)}{\left(1-B_{j}\right)^{2} y_{j}} h_{i}\left(y_{i}\right) d y_{i} d y_{j} \\
\leq & \frac{144 \sigma_{i}^{4} \ell_{0}}{m^{2}\left(1-B_{j}\right)^{2} s_{i j}} \int_{y_{i}} \int_{x=0}^{1} \exp \left(\frac{n(m-1)}{2} g_{1}(x)\right) x d x h_{i}\left(y_{i}\right) d y_{i} \\
\leq & \frac{288 \sigma_{i}^{4} \ell_{0}}{m^{2}\left(1-B_{j}\right)^{2} s_{i j}} \times \frac{1}{n(m-1)} . \tag{A.8}
\end{align*}
$$

Combining (A.6)-(A.8) yields that

$$
\begin{equation*}
J_{1}=O\left(\frac{1}{n}\right) \tag{A.9}
\end{equation*}
$$

Let $D_{2}=\left\{\left(y_{i}, y_{j}\right) \in A_{i j 2} \left\lvert\, y_{j}<\frac{s_{i j}}{2}\right.\right\}$ and $C_{2}=\left\{\left(y_{i}, y_{j}\right) \in A_{i j 2} \left\lvert\, y_{j} \geq \frac{s_{i j}}{2}\right.\right\}$. Thus,

$$
\begin{equation*}
J_{2}=\iint_{D_{2}} \alpha_{2}\left(y_{i}, y_{j}, n\right) d y_{i} d y_{j}+\iint_{C_{2}} \alpha_{2}\left(y_{i}, y_{j}, n\right) d y_{i} d y_{j}=J_{21}+J_{22} \tag{A.10}
\end{equation*}
$$

Note that $g_{2}(x)$ is increasing in $x$ for $x>0$. Thus, on $D_{2}, g_{2}\left(\frac{m t\left(y_{i}, y_{j}\right)}{2 B_{i} \sigma_{i}^{2}}\right) \geq g_{2}\left(\frac{m t\left(0, \frac{s_{i j}}{2}\right)}{2 B_{i} \sigma_{i}^{2}}\right)=$ $g_{2}\left(\frac{m c_{2}}{12 B_{i} \sigma_{i}^{2}}\right)>0$. By a discussion similar to that of $J_{11}$, we can obtain:

$$
\begin{equation*}
J_{21} \leq \exp \left(\frac{-n(m-1)}{2} g_{2}\left(\frac{m c_{2}}{12 B_{i} \sigma_{i}^{2}}\right)\right) \tau^{*^{2}} \tag{A.11}
\end{equation*}
$$

For the term $J_{22}$, by a discussion similar to that of $J_{12}$, by changing variable by letting $x=\frac{m t\left(y_{i}, y_{j},\right.}{2 B_{i} \sigma_{i}^{2}}$ and Lemma B.5, we have

$$
\begin{align*}
J_{22}= & 24 \iint_{C_{2}} \exp \left\{\frac{-n(m-1)}{2} g_{2}\left(\frac{m t\left(y_{i}, y_{j}\right)}{2 B_{i} \sigma_{i}^{2}}\right)\right\} \frac{m t\left(y_{i}, y_{j}\right)}{2 B_{i} \sigma_{i}^{2}}\left|\frac{\partial}{\partial y_{j}} \frac{m t\left(y_{i}, y_{j}\right)}{2 B_{i} \sigma_{i}^{2}}\right| \\
& \times \frac{12 B_{i}^{2} \sigma_{i}^{4} h_{j}\left(y_{j}\right)}{m^{2}\left(1-B_{j}\right)^{2} y_{j}} h_{i}\left(y_{i}\right) d y_{j} d y_{i} \\
\leq & \frac{288 B_{i}^{2} \sigma_{i}^{4} \ell_{0}}{m^{2}\left(1-B_{j}\right)^{2} s_{i j}} \int_{y_{i}} \int_{x=0}^{\infty} \exp \left(\frac{-n(m-1)}{2} g_{2}(x)\right) x d x h_{i}\left(y_{i}\right) d y_{i} \\
\leq & \frac{288 B_{i}^{2} \sigma_{i}^{4} \ell_{0}}{m^{2}\left(1-B_{j}\right)^{2} s_{i j}}\left[\frac{2}{n(m-1)}+\frac{16}{n^{2}(m-1)^{2}}\right]=O\left(\frac{1}{n}\right) . \tag{A.12}
\end{align*}
$$

Combining (A.10)-(A.12) yields that

$$
\begin{gather*}
J_{2}=O\left(\frac{1}{n}\right)  \tag{A.13}\\
J_{3}=\iint_{D_{2}} \alpha_{3}\left(y_{i}, y_{j}, n\right) d y_{i} d y_{j}+\iint_{C_{2}} \alpha_{3}\left(y_{i}, y_{j}, n\right) d y_{i} d y_{j}=J_{31}+J_{32} \tag{A.14}
\end{gather*}
$$

Note that $\frac{m t\left(y_{i}, y_{j}\right)}{2 B_{i} \sigma_{i}+2 m t\left(y_{i}, y_{j}\right)}$ is increasing in $y_{i}$ and decreasing in $y_{j}$ for $\left(y_{i}, y_{j}\right)$ in $D_{2}$. Thus, on $D_{2}, \frac{m t\left(y_{i}, y_{j}\right)}{2 B_{i} \sigma_{i}^{2}+2 m t\left(y_{i}, y_{j}\right)} \geq \frac{m t\left(0, \frac{s_{i j}}{2}\right)}{2 B_{i} \sigma_{i}^{2}+2 m t\left(0, \frac{s_{i j}}{2}\right)} \equiv c_{4}>0$. Therefore,

$$
\begin{equation*}
J_{31} \leq \exp \left(\frac{n}{2} g_{1}\left(c_{4}\right)\right) \tau^{*^{2}} \tag{A.15}
\end{equation*}
$$

Let $y_{i 0}$ be the point such that $\left(1-B_{i}\right) \sigma_{i}^{2}-m t\left(y_{i 0}, s_{i j}\right)=0$. By the definition of $C_{2}$, if $\left(y_{i}, y_{j}\right)$ is in $C_{2}$, then $0<y_{i}<y_{i 0}$ and $y_{j} \geq \frac{s_{i j}}{2}$. Thus for $\left(y_{i}, y_{j}\right)$ in $C_{2}$,
$\frac{m t\left(y_{i}, y_{j}\right)}{2 B_{i} \sigma_{i}^{2}+2 m t\left(y_{i}, y_{j}\right)} \geq \frac{m t\left(y_{i}, y_{j}\right)}{2 B_{i} \sigma_{i}^{2}+2 m t\left(y_{i}, \frac{s_{i j}}{2}\right)}$. Therefore,

$$
\begin{equation*}
J_{32} \leq \iint_{C_{2}} 24 \exp \left\{\frac{n}{2} g_{1}\left(\frac{m t\left(y_{i}, y_{j}\right)}{2 B_{i} \sigma_{i}^{2}+2 m t\left(y_{i 0}, \frac{s_{i j}}{2}\right)}\right)\right\} t\left(y_{i}, y_{j}\right) h_{i}\left(y_{i}\right) h_{j}\left(y_{j}\right) d y_{i} d y_{j} \equiv J_{32}^{*} \tag{A.16}
\end{equation*}
$$

Now, the form of $J_{32}^{*}$ is similar to that of $J_{12}$. Thus, following a discussion similar to that of $J_{12}$, we can obtain:

$$
\begin{equation*}
J_{32} \leq J_{32}^{*} \leq \frac{144\left[2 B_{i} \sigma_{i}^{2}+2 m t\left(y_{i 0}, \frac{s_{i j}}{2}\right)\right]^{2} \ell_{0}}{m^{2}\left(1-B_{j}\right)^{2} s_{i j}} \times \frac{1}{n} \tag{A.17}
\end{equation*}
$$

Combining (A.14)-(A.17), it leads to

$$
\begin{equation*}
J_{3}=O\left(\frac{1}{n}\right) \tag{A.18}
\end{equation*}
$$

Define $D_{3}=\left\{\left(y_{i}, y_{j}\right) \in A_{i j 3} \left\lvert\, y_{j}<\frac{s_{i j}}{2}\right.\right\}$ and $C_{3}=\left\{\left(y_{i}, y_{j}\right) \in A_{i j 3} \left\lvert\, y_{j} \geq \frac{s_{i j}}{2}\right.\right\}$. Thus,

$$
\begin{equation*}
J_{4}=\iint_{D_{3}} \alpha_{4}\left(y_{i}, y_{j}, n\right) d y_{i} d y_{j}+\iint_{C_{3}} \alpha_{4}\left(y_{i}, y_{j}, n\right) d y_{i} d y_{j}=J_{41}+J_{42} \tag{A.19}
\end{equation*}
$$

On $\quad D_{3}, \quad \frac{t\left(y_{i}, y_{j}\right)}{4 B_{i} v_{i}^{2}} \geq \frac{t\left(y_{i} B_{i j}\right)}{4 B_{i} v_{i}^{2}}=\frac{\left(1-B_{i}\right)^{2}}{24 B_{i}}+\frac{\psi_{i}(0)-\psi_{j}\left(\frac{s_{i j}}{2}\right)}{44 B_{i} y_{i}^{2}} \geq \frac{\left(1-B_{i}\right)^{2}}{24 B_{i}}$ since $\psi_{i}(0)-\psi_{j}\left(\frac{s_{i j}}{2}\right)>0$.
By increasing property of $g_{2}(x)$ for $x>0$, we can obtain:

$$
\begin{equation*}
J_{41} \leq \exp \left\{\frac{-n(m-1)}{2} g_{2}\left(\frac{\left(1-B_{i}\right)^{2}}{24 B_{i}}\right)\right\} \tau^{*^{2}} \tag{A.20}
\end{equation*}
$$

For $J_{42}$, following a discussion similar to that of $J_{22}$, we obtain:

$$
\begin{align*}
J_{42}= & 24 \iint_{C_{3}} \exp \left\{\frac{-n(m-1)}{2} g_{2}\left(\frac{t\left(y_{i}, y_{j}\right)}{4 B_{i} y_{i}^{2}}\right)\right\}\left\{\frac{t\left(y_{i}, y_{j}\right)}{4 B_{i} y_{i}^{2}}\left|\frac{\partial}{\partial y_{j}} \frac{t\left(y_{i}, y_{j}\right)}{4 B_{i} y_{i}^{2}}\right|\right. \\
& \times \frac{48 B_{i}^{2} y_{i}^{4}}{\left(1-B_{j}\right)^{2} y_{j}} h_{i}\left(y_{i}\right) h_{j}\left(y_{j}\right) d y_{i} d y_{j} \\
\leq & \frac{2304 B_{i}^{2}}{\left(1-B_{j}\right)^{2} s_{i j}} \int_{0}^{\infty} \exp \left(\frac{-n(m-1)}{2} g_{2}(x)\right) x d x \int_{-\infty}^{\infty} y_{i}^{4} h_{i}\left(y_{i}\right) d y_{i} \\
\leq & \frac{2304 B_{i}^{2}}{\left(1-B_{j}\right)^{2} s_{i j}}\left[\frac{2}{n(m-1)}+\frac{16}{n^{2}(m-1)^{2}}\right] M_{4}, \tag{A.21}
\end{align*}
$$

where $M_{4}=\max _{1 \leq i \leq k}\left\{E Y_{i}^{4}\right\}$.
Combining (A.19)-(A.21) yields that

$$
\begin{equation*}
J_{4}=O\left(\frac{1}{n}\right) \tag{A.22}
\end{equation*}
$$

On $\quad A_{i j 3}, \quad 0 \leq y_{j} \leq s_{i j}$. Thus, we have: $\frac{t\left(y_{i}, y_{j}\right)}{4 B_{i} v_{i}^{2}+2 t\left(y_{i}, y_{j}\right)} \geq \frac{t\left(y_{i}, s_{i j}\right)}{4 B_{i} v_{i}^{2}+2 t\left(y_{i}, s_{i j}\right)}=$ $\frac{y_{i}^{2}\left(1-B_{i}\right)^{2}+\psi_{i}(0)-\psi_{j}\left(s_{i j}\right)}{y_{i}^{2}\left[4 B_{i}+2\left(1-B_{i}\right)^{2}\right]+2\left[\psi_{i}(0)-\psi_{j}\left(s_{i j}\right)\right]}=\frac{\left(1-B_{i}\right)^{2}}{4 B_{i}+2\left(1-B_{i}\right)^{2}}$, since $\psi_{i}(0)-\psi_{j}\left(s_{i j}\right)=0$. Since $g_{1}(x)$ is decreasing in $(0,1)$, therefore,

$$
\begin{align*}
J_{5} & =\iint_{A_{i j 3}} 24 \exp \left(\frac{n}{2} g_{1}\left(\frac{t\left(y_{i}, y_{j}\right)}{4 B_{i} y_{i}^{2}+2 t\left(y_{i}, y_{j}\right)}\right)\right) t\left(y_{i}, y_{j}\right) h_{i}\left(y_{i}\right) h_{j}\left(y_{j}\right) d y_{i} d y_{j} \\
& \leq \iint_{A_{i j 3}} 24 \exp \left(\frac{n}{2} g_{1}\left(\frac{\left(1-B_{i}\right)^{2}}{4 B_{i}+2\left(1-B_{i}\right)^{2}}\right)\right) t\left(y_{i}, y_{j}\right) h_{i}\left(y_{i}\right) h_{j}\left(y_{j}\right) d y_{i} d y_{j} \\
& \leq 24 \exp \left\{\frac{n}{2} g_{1}\left(\frac{\left(1-B_{i}\right)^{2}}{4 B_{i}+2\left(1-B_{i}\right)^{2}}\right)\right\} \tau^{*^{2}} . \tag{A.23}
\end{align*}
$$

Combining (A.5), (A.9), (A.13), (A.18), (A.22), and (A.23), we conclude that under Case 1 that $s_{i j}>0$,

$$
\begin{equation*}
I_{i j}=O\left(\frac{1}{n}\right) \tag{A.24}
\end{equation*}
$$

Case 2. $s_{i j}=0$.
When $s_{i j}=0, \psi_{j}(0)-\psi_{i}(0) \geq 0$. For $\left(y_{i}, y_{j}\right)$ in $A_{i j}, \psi_{i}\left(y_{i}\right)=\psi_{i}(0)+\left(1-B_{i}\right)^{2} y_{i}^{2}>$ $\psi_{j}(0)+\left(1-B_{j}\right)^{2} y_{j}^{2}=\psi_{j}\left(y_{j}\right)$. Thus, $\left|y_{i}\right| \geq \frac{\left(1-B_{j}\right)}{\left(1-B_{i}\right)}\left|y_{j}\right|$.

Define $D_{1}(n)=\left\{\left(y_{i}, y_{j}\right) \in A_{i j 1} \left\lvert\, y_{j} \geq \frac{1}{n}\right.\right\} \quad$ and $\quad C_{1}(n)=\left\{\left(y_{i}, y_{j}\right) \in A_{i j 1} \left\lvert\, y_{j}<\frac{1}{n}\right.\right\}$. Thus,

$$
\begin{equation*}
J_{1}=\iint_{D_{1}(n)} \alpha_{1}\left(y_{i}, y_{j}, n\right) d y_{i} d y_{j}+\iint_{C_{1}(n)} \alpha_{1}\left(y_{i}, y_{j}, n\right) d y_{i} d y_{j}=J_{11}(n)+J_{12}(n) \tag{A.25}
\end{equation*}
$$

On $D_{1}(n), \frac{\partial t\left(y_{i} y_{j}\right)}{\partial y_{i}}=\frac{2}{6}\left(1-B_{i}\right)^{2} y_{i} \geq \frac{1}{3}\left(1-B_{i}\right)\left(1-B_{j}\right) y_{j}$. Thus,

$$
\begin{align*}
J_{11}(n) \leq & 24 \iint_{D_{1}(n)} \exp \left(\frac{n(m-1)}{2} g_{1}\left(\frac{m t\left(y_{i}, y_{j}\right)}{\sigma_{i}^{2}}\right)\right) \frac{m t\left(y_{i}, y_{j}\right)}{\sigma_{i}^{2}}\left|\frac{\partial}{\partial y_{i}} \frac{m t\left(y_{i}, y_{j}\right)}{\sigma_{i}^{2}}\right| \frac{\sigma_{i}^{4}}{m^{2}} \\
& \times \frac{3 h_{i}\left(y_{i}\right) h_{j}\left(y_{j}\right)}{\left(1-B_{i}\right)\left(1-B_{j}\right) y_{j}} d y_{i} d y_{j} \\
\leq & \frac{72 \sigma_{i}^{4} \ell_{0}^{2}}{m^{2}\left(1-B_{i}\right)\left(1-B_{j}\right)} \int_{\frac{1}{n}}^{a_{j}} \int_{0}^{1} \exp \left(\frac{n(m-1)}{2} g_{1}(x)\right) x d x \frac{1}{y_{j}} d y_{j} \\
\leq & \frac{144 \sigma_{i}^{4} \ell_{0}^{2}}{m^{2}\left(1-B_{i}\right)\left(1-B_{j}\right)} \frac{1}{n(m-1)}\left[\ln n+\ln a_{j}\right]=O\left(\frac{\ln n}{n}\right) . \tag{A.26}
\end{align*}
$$

Also, by the definition of $C_{1}(n)$, we can obtain

$$
\begin{equation*}
J_{12}(n) \leq \frac{\ell_{0} \tau^{*^{2}}}{n} . \tag{A.27}
\end{equation*}
$$

Therefore, we have

$$
\begin{equation*}
J_{1}=O\left(\frac{\ln n}{n}\right) \tag{A.28}
\end{equation*}
$$

Let $D_{2}(n)=\left\{\left(y_{i}, y_{j}\right) \in A_{i j 2} \left\lvert\, y_{j} \geq \frac{1}{n}\right.\right\}$ and $C_{2}(n)=\left\{\left(y_{i}, y_{j}\right) \in A_{i j 2} \left\lvert\, y_{j}<\frac{1}{n}\right.\right\}$. Thus,

$$
\begin{equation*}
J_{2}=\iint_{D_{2}(n)} \alpha_{2}\left(y_{i}, y_{j}, n\right) d y_{i} d y_{j}+\iint_{C_{2}(n)} \alpha_{2}\left(y_{i}, y_{j}, n\right) d y_{i} d y_{j}=J_{21}(n)+J_{22}(n) \tag{A.29}
\end{equation*}
$$

where

$$
\begin{equation*}
J_{22}(n) \leq \frac{\ell_{0} \tau^{*^{2}}}{n} \tag{A.30}
\end{equation*}
$$

and by a discussion similar to that of $J_{11}(n)$, we can obtain

$$
\begin{equation*}
J_{21}(n)=O\left(\frac{\ln n}{n}\right) \tag{A.31}
\end{equation*}
$$

Therefore, we have

$$
\begin{gather*}
J_{2}=O\left(\frac{\ln n}{n}\right) .  \tag{A.32}\\
J_{3}=\iint_{D_{2}(n)} \alpha_{3}\left(y_{i}, y_{j}, n\right) d y_{i} d y_{j}+\iint_{C_{2}(n)} \alpha_{3}\left(y_{i}, y_{j}, n\right) d y_{i} d y_{j}=J_{31}(n)+J_{32}(n), \tag{A.33}
\end{gather*}
$$

where

$$
\begin{equation*}
J_{32}(n) \leq \frac{\ell_{0} \tau^{*^{2}}}{n} . \tag{A.34}
\end{equation*}
$$

Note that for $\left(y_{i}, y_{j}\right)$ in $D_{2}(n),\left(1-B_{i}\right) \sigma_{i}^{2}-m t\left(y_{i}, y_{j}\right)>0$. Thus, $\frac{\partial}{\partial y_{i}} \frac{m t\left(y_{i}, y_{j}\right)}{2 B_{i} \sigma_{i}^{2}+2 m t\left(y_{i}, y_{j}\right)}=$ $\frac{24 B_{i} \sigma_{i}^{2}\left(1-B_{i}\right)^{2} y_{i}}{\left[12 B_{i} \sigma_{i}^{2}+2 m\left(y_{i}\left(y_{i}\right)-\psi_{j}\left(y_{j}\right)\right)\right]^{2}} \geq \frac{24 m B_{i}\left(1-B_{i}\right)\left(1-B_{j}\right) y_{j}}{\left(10 B_{i}+2\right)^{2} \sigma_{i}^{2}}$. By the preceding inequality and by changing variable taking $x=\frac{m t\left(y_{i}, y_{j}\right)}{2 B_{i} \sigma_{i}+2 m t\left(y_{i}, y_{j}\right)}$, we can obtain:

$$
\begin{align*}
J_{31}(n) & \leq 24 \int_{\frac{1}{n}}^{a_{j}} \int_{0}^{1} \exp \left(\frac{n}{2} g_{1}(x)\right) x d x \frac{2 \sigma_{i}^{2}}{m} \times \frac{\ell_{0}^{2}\left(10 B_{i}+2\right)^{2} \sigma_{i}^{2}}{24 m B_{i}\left(1-B_{i}\right)\left(1-B_{j}\right) y_{j}} d y_{j} \\
& =\frac{2 \sigma_{i}^{2} \ell_{0}^{2}\left(10 B_{i}+2\right)^{2} \sigma_{i}^{2}}{m^{2} B_{i}\left(1-B_{i}\right)\left(1-B_{j}\right)} \times \frac{1}{n}\left[\ln n+\ln a_{j}\right] \\
& =O\left(\frac{\ln n}{n}\right) . \tag{A.35}
\end{align*}
$$

Hence, we obtain

$$
\begin{equation*}
J_{3}=O\left(\frac{\ln n}{n}\right) \tag{A.36}
\end{equation*}
$$

Let $D_{3}=\left\{\left(y_{i}, y_{j}\right) \in A_{i j 3} \mid y_{i} \geq 2 a_{i}\right\}$ and $C_{3}=\left\{\left(y_{i}, y_{j}\right) \in A_{i j 3} \mid y_{i}<2 a_{i}\right\}$. Thus,

$$
\begin{equation*}
J_{4}=\iint_{D_{3}} \alpha_{4}\left(y_{i}, y_{j}, n\right) d y_{i} d y_{j}+\iint_{C_{3}} \alpha_{4}\left(y_{i}, y_{j}, n\right) d y_{i} d y_{j}=J_{41}+J_{42} \tag{A.37}
\end{equation*}
$$

Since $\psi_{j}(0)-\psi_{i}(0) \geq 0$, on $D_{3}, \frac{t\left(y_{i}, y_{j}\right)}{4 B_{i} v_{i}^{2}}$ is increasing in $y_{i}$ for $y_{i}>0$. Thus, $\frac{t\left(y_{i}, y_{j}\right)}{4 B_{i} v_{i}^{2}} \geq$ $\frac{t\left(2 a_{i}, y_{j}\right)}{16 B_{i} a_{i}^{2}} \geq \frac{t\left(2 a_{i}, a_{j}\right)}{16 B_{i} a_{i}^{2}}>0$. Also, $g_{2}(x)$ is increasing in $x$ for $x>0$, so, $g_{2}\left(\frac{t\left(y_{i}, y_{j}\right)}{4 B_{i} y_{i}^{2}}\right) \geq$ $g_{2}\left(\frac{t\left(2 a_{i}, a_{j}\right)}{16 B_{i} a_{i}^{2}}\right)$. Hence,

$$
\begin{equation*}
J_{41} \leq \exp \left\{\frac{-n(m-1)}{2} g_{2}\left(\frac{t\left(2 a_{i}, a_{j}\right)}{16 B_{i} a_{i}^{2}}\right)\right\} \tau^{*^{2}} \tag{A.38}
\end{equation*}
$$

On $C_{3}, y_{i}<2 a_{i}$. Thus, $\frac{t\left(y_{i}, y_{j}\right)}{4 B_{i} y_{i}^{2}} \geq \frac{t\left(y_{i}, y_{j}\right)}{16 B_{i} a_{i}^{2}}$. Therefore analogous to $J_{2}$, we have

$$
\begin{align*}
J_{42} & \leq 24 \iint_{C_{3}} \exp \left\{\frac{-n(m-1)}{2} g_{2}\left(\frac{t\left(y_{i}, y_{j}\right)}{16 B_{i} a_{i}^{2}}\right)\right\} t\left(y_{i}, y_{j}\right) h_{i}\left(y_{i}\right) h_{j}\left(y_{j}\right) d y_{i} d y_{j} \\
& =O\left(\frac{\ln n}{n}\right) \tag{A.39}
\end{align*}
$$

Combining (A.37)-(A.39) yields that

$$
\begin{gather*}
J_{4}=O\left(\frac{\ln n}{n}\right)  \tag{A.40}\\
J_{5}=\iint_{D_{3}} \alpha_{5}\left(y_{i}, y_{j}, n\right) d y_{i} d y_{j}+\iint_{C_{3}} \alpha_{5}\left(y_{i}, y_{j}, n\right) d y_{i} d y_{j}=J_{51}+J_{52} \tag{A.41}
\end{gather*}
$$

On $A_{i j 3}, \frac{t\left(y_{i}, y_{j}\right)}{4 B_{i} v_{i}^{2}+2 t\left(y_{i}, y_{i}\right)}$ is increasing in $y_{i}$ for $y_{i}>0$. Thus, on $D_{3}, \frac{t\left(y_{i}, y_{j}\right)}{4 B_{i} y_{i}^{2}+2 t\left(y_{i}, y_{j}\right)} \geq$ $\frac{t\left(2 a_{i}, y_{j}\right)}{16 B_{i} a_{i}^{2}+2 t\left(2 a_{i}, y_{j}\right)} \geq \frac{t\left(2 a_{i}, a_{j}\right)}{16 B_{i} a_{i}^{2}+2 t\left(2 a_{i}, a_{j}\right)}$. Therefore,

$$
\begin{equation*}
J_{51} \leq \exp \left\{\frac{n}{2} g_{1}\left(\frac{t\left(2 a_{i}, a_{j}\right)}{16 B_{i} a_{i}^{2}+2 t\left(2 a_{i}, a_{j}\right)}\right)\right\} \tau^{*^{2}} \tag{A.42}
\end{equation*}
$$

On $C_{3}, \frac{t\left(y_{i}, y_{j}\right)}{4 B_{i} y_{i}^{2}+2 t\left(y_{i}, y_{j}\right)} \geq \frac{t\left(y_{i}, y_{j}\right)}{16 B_{i} a_{i}^{2}+2 t\left(2 a_{i}, 0\right)}$. Again, analogous to $J_{1}$, we can obtain

$$
\begin{align*}
J_{52} & \leq 24 \iint_{C_{3}} \exp \left\{\frac{n}{2} g_{1}\left(\frac{t\left(y_{i}, y_{j}\right)}{16 B_{i} a_{i}^{2}+2 t\left(2 a_{i}, 0\right)}\right)\right\} t\left(y_{i}, y_{j}\right) h_{i}\left(y_{i}\right) h_{j}\left(y_{j}\right) d y_{i} d y_{j} \\
& =O\left(\frac{\ln n}{n}\right) \tag{A.43}
\end{align*}
$$

Combining the preceding results leads to

$$
\begin{equation*}
J_{5}=O\left(\frac{\ln n}{n}\right) \tag{A.44}
\end{equation*}
$$

Now combining (A.5), (A.28), (A.32), (A.36), (A.40), and (A.44), we conclude that under Case 2 that $s_{i j}=0$,

$$
\begin{equation*}
I_{i j}=O\left(\frac{\ln n}{n}\right) \tag{A.45}
\end{equation*}
$$

Finally, since there are $\frac{k(k-1)}{2}$ terms in $I$, each of them has order $O\left(\frac{\ln n}{n}\right)$, therefore we conclude that $I=O\left(\frac{\ln ^{2} n}{n}\right)$.

## Appendix B

Lemma A. 1 is cited from Liang (1997).
Lemma B.1. Let $S$ be a $\chi^{2}(n)$ random variable. Then, the following inequalities hold.
(a) $P\left\{\frac{S}{n}-1 \leq-c\right\} \leq \exp \left\{\frac{n}{2}[c+\ln (1-c)]\right\}$ if $0 \leq c<1, P\left\{\frac{S}{n}-1 \leq-c\right\}=0$ if $c \geq 1$.
(b) $P\left\{\frac{s}{n}-1 \geq c\right\} \leq \exp \left\{\frac{-n}{2}[c-\ln (1+c)]\right\}$ for $c>0$.

## Corollary B.1.

(a) $\frac{n(m-1) W_{i}(n)}{\sigma_{i}^{2}} \sim \chi^{2}(n(m-1))$. Thus,

$$
\begin{aligned}
& P\left\{\frac{W_{i}(n)}{\sigma_{i}^{2}}-1 \leq-c\right\} \begin{cases}\leq \exp \left\{\frac{n(m-1)}{2}[c+\ln (1-c)]\right\} & \text { if } 0 \leq c<1, \\
=0 & \text { if } c \geq 1 .\end{cases} \\
& P\left\{\frac{W_{i}(n)}{\sigma_{i}^{2}}-1 \geq c\right\} \leq \exp \left\{\frac{-n(m-1)}{2}[c-\ln (1+c)]\right\} \text { for } c>0 .
\end{aligned}
$$

(b) $\frac{n S_{i}(n)}{\tau_{i}^{2}+\sigma_{i}^{2} / m} \sim \chi^{2}(n)$. Thus,

$$
\begin{aligned}
& P\left\{\frac{S_{i}(n)}{\tau_{i}^{2}+\sigma_{i}^{2} / m}-1 \leq-c\right\} \begin{cases}\leq \exp \left\{\frac{n}{2}[c+\ln (1-c)]\right\} & \text { if } 0 \leq c<1, \\
=0 & \text { if } c \geq 1\end{cases} \\
& P\left\{\frac{S_{i}(n)}{\tau_{i}^{2}+\sigma_{i}^{2} / m}-1 \geq c\right\} \leq \exp \left\{\frac{-n}{2}[c-\ln (1+c)]\right\} \quad \text { for } c>0
\end{aligned}
$$

## Lemma B.2.

(a) For $b>0$ and $B_{i}+b<1$,

$$
\begin{aligned}
& P\left\{B_{i n}-B_{i}>b\right\} \\
& \quad \leq P\left\{\frac{W_{i}(n)}{\sigma_{i}^{2}}-1>\frac{b}{2 B_{i}}\right\}+P\left\{\frac{S_{i}(n)}{\tau_{i}^{2}+\sigma_{i}^{2} / m}-1<\frac{-b}{2\left(B_{i}+b\right)}\right\} \\
& \quad \leq \exp \left\{\frac{-n(m-1)}{2}\left[\frac{b}{2 B_{i}}-\ln \left(1+\frac{b}{2 B_{i}}\right)\right]\right\} \\
& \quad+\exp \left\{\frac{n}{2}\left[\frac{b}{2\left(B_{i}+b\right)}+\ln \left(1-\frac{b}{2\left(B_{i}+b\right)}\right)\right]\right\},
\end{aligned}
$$

and

$$
P\left\{B_{i n}-B_{i}>b\right\}=0 \text { if } B_{i}+b \geq 1
$$

(b) For $b>0$ such that $-b+B_{i}>0$,

$$
\begin{aligned}
& P\left\{B_{i n}-B_{i}<-b\right\} \\
& \quad \leq P\left\{\frac{W_{i}(n)}{\sigma_{i}^{2}}-1<\frac{-b}{2 B_{i}}\right\}+P\left\{\frac{S_{i}(n)}{\tau_{i}^{2}+\sigma_{i}^{2} / m}-1>\frac{b}{2\left(B_{i}-b\right)}\right\} \\
& \quad \leq \exp \left\{\frac{n(m-1)}{2}\left[\frac{b}{2 B_{i}}+\ln \left(1-\frac{b}{2 B_{i}}\right)\right]\right\} \\
& \quad+\exp \left\{\frac{-n}{2}\left[\frac{b}{2\left(B_{i}-b\right)}-\ln \left(1+\frac{b}{2\left(B_{i}-b\right)}\right)\right]\right\},
\end{aligned}
$$

and

$$
P\left\{B_{i n}-B_{i}<-b\right\}=0 \text { if } B_{i}-b \leq 0 .
$$

Lemma B.3. For $c>0$, and $\psi_{i}\left(y_{i}\right)-3 c>0$, then,

$$
\begin{aligned}
P & \left\{\psi_{i n}\left(y_{i}\right)-\psi_{i}\left(y_{i}\right)<-3 c\right\} \\
\leq & P\left\{W_{i}(n)-\sigma_{i}^{2}<-m c\right\}+P\left\{B_{i n}-B_{i}>\frac{m c}{\sigma_{i}^{2}}\right\}+P\left\{B_{i n}-B_{i}>\frac{c}{2 y_{i}^{2}}\right\} \\
& \leq \exp \left\{\frac{n(m-1)}{2}\left[\frac{m c}{\sigma_{i}^{2}}+\ln \left(1-\frac{m c}{\sigma_{i}^{2}}\right)\right]\right\} I\left(\sigma_{i}^{2}-m c\right) \\
& +\exp \left\{\frac{-n(m-1)}{2}\left[\frac{m c}{2 B_{i} \sigma_{i}^{2}}-\ln \left(1+\frac{m c}{2 B_{i} \sigma_{i}^{2}}\right)\right]\right\} I\left(1-B_{i}-\frac{m c}{\sigma_{i}^{2}}\right) \\
& +\exp \left\{\frac{n}{2}\left[\frac{m c}{2 B_{i} \sigma_{i}^{2}+2 m c}+\ln \left(1-\frac{m c}{2 B_{i} \sigma_{i}^{2}+2 m c}\right)\right]\right\} I\left(1-B_{i}-\frac{m c}{\sigma_{i}^{2}}\right) \\
& +\exp \left\{\frac{-n(m-1)}{2}\left[\frac{c}{4 B_{i} y_{i}^{2}}-\ln \left(1+\frac{c}{4 B_{i} y_{i}^{2}}\right)\right]\right\} I\left(1-B_{i}-\frac{c}{2 y_{i}^{2}}\right) \\
& +\exp \left\{\frac{n}{2}\left[\frac{c}{4 B_{i} y_{i}^{2}+2 c}+\ln \left(1-\frac{c}{4 B_{i} y_{i}^{2}+2 c}\right]\right\} I\left(1-B_{i}-\frac{c}{2 y_{i}^{2}}\right),\right.
\end{aligned}
$$

where $I(x)=1$ if $x>0$, and 0 otherwise, and $P\left\{W_{\text {in }}\left(y_{i}\right)-\psi_{i}\left(y_{i}\right)<-3 c\right\}=0$ if $\psi_{i}\left(y_{i}\right)-3 c \leq 0$.

For $0<x<1$, define $g_{1}(x)=x+\ln (1-x)$. For $x>0$, define $g_{2}(x)=$ $x-\ln (1+x)$.

## Lemma B.4.

(a) $g_{1}(x)$ is decreasing in $(0,1)$ and $g_{1}(x) \leq \frac{-x^{2}}{2}$ in $(0,1)$.
(b) For $0<t<1$, and $c>0$,

$$
\int_{0}^{t} x \exp (c n(x+\ln (1-x))) d x=\int_{0}^{t} x \exp \left(c n g_{1}(x)\right) d x \leq \frac{1}{n c} .
$$

## Lemma B.5.

(a) $g_{2}(x)$ is increasing in $x$ for $x>0, g_{2}(x) \geq \frac{x^{2}}{4}$ for $0<x \leq 1$ and $g_{2}(x) \geq \frac{x}{4}+c_{1}$ for $x \geq 1$, where $c_{1}=\frac{3}{4}-\ln 2>0$.
(b) $0<t<1$, and $c>0$,

$$
\int_{0}^{t} x \exp (-c n(x-\ln (1+x))) d x=\int_{0}^{t} x \exp \left(-c n g_{2}(x)\right) d x \leq \frac{2}{n c}
$$

(c) For $t>1$,

$$
\int_{1}^{t} x \exp \left(-c n g_{2}(x)\right) d x \leq \frac{16}{n^{2} c^{2}}
$$

## Lemma B.6.

$$
\begin{aligned}
& \iint_{A_{i j}}\left[\psi_{i}\left(y_{i}\right)-\psi_{j}\left(y_{j}\right)\right] h_{i}\left(y_{i}\right) h_{j}\left(y_{j}\right) d y_{i} d y_{j} \\
& \quad \leq \int \psi_{i}\left(y_{i}\right) h_{i}\left(y_{i}\right) d y_{i}=E\left[\Theta_{i}^{2}\right]=\tau_{i}^{2} \leq \tau^{*^{2}}
\end{aligned}
$$

where $\tau^{*^{2}}=\max \left(\tau_{1}^{2}, \ldots, \tau_{k}^{2}\right)$.
